## About This Book

The server-requester programming interface (SRPI) of the TSO/E Enhanced Connectivity Facility lets you write *server* programs. The servers can provide MVS host computer services, data, and resources to *requester* programs on IBM personal computers.

This book tells you how to write an MVS server to receive a service request, process the request, and return a reply to the requester. The book includes a sample server, along with information on installing, testing, and debugging servers.

This book also includes information about how to write programs called *access method drivers*. Access method drivers allow the MVS host to manage server-requester communications across different hardware connections with the personal computer (PC).

---

## Who Should Use This Book

This book is intended for:

- Application programmers who design, write, and test MVS servers and server initialization/termination programs.
- System programmers who allocate and initialize the data sets that make MVS servers and diagnosis information available to users.
- System programmers who write or install access method drivers for use with the TSO/E Enhanced Connectivity Facility.

The audience must be familiar with MVS programming conventions and the assembler programming language.

---

## How This Book Is Organized

- “Chapter 1. Introduction” on page 1 describes MVS servers and how they provide MVS services, data, and resources to requester programs.
- “Chapter 2. Designing and Writing a Server” on page 7 describes the input a server receives, the tools a server can use to process requests, and the output a server must provide.
- “Chapter 3. Designing and Writing a Server Initialization/Termination Program” on page 35 describes how to write a program that initializes one or more servers, obtains resources for them, and terminates them.
- “Chapter 4. Writing an Access Method Driver” on page 53 describes how to write a program that can manage server-requester communications across specific PC-to-Host hardware connections.
- “Chapter 5. Installing Programs and Data Sets for Use with MVSSERV” on page 59 describes how to allocate and initialize the data sets that give users access to servers, initialization/termination programs, access method drivers, and diagnosis information.
- “Chapter 6. Testing and Diagnosis” on page 65 explains how to use the MVSSERV command to test a server. This chapter also tells how to use the MVSSERV trace data set to diagnose server problems.
- “Chapter 7. Macro Syntax and Parameters” on page 69 describes the syntax and parameters of the macros you can use in MVSSERV programming.

- “Chapter 8. MVSSERV Return Codes” on page 79 describes the return codes that you may receive from the MVSSERV macros.

---

## Where to Find More Information

Please see *z/OS Information Roadmap* for an overview of the documentation associated with z/OS, including the documentation available for z/OS TSO/E.

## Accessing Licensed Books on the Web

z/OS licensed documentation in PDF format is available on the Internet at the IBM Resource Link Web site at:

<http://www.ibm.com/servers/resourceLink>

Licensed books are available only to customers with a z/OS license. Access to these books requires an IBM Resource Link Web userid and password, and a key code. With your z/OS order you received a memo that includes this key code.

To obtain your IBM Resource Link Web userid and password log on to:

<http://www.ibm.com/servers/resourceLink>

To register for access to the z/OS licensed books:

1. Log on to Resource Link using your Resource Link userid and password.
2. Click on **User Profiles** located on the left-hand navigation bar.
3. Click on **Access Profile**.
4. Click on **Request Access to Licensed books**.
5. Supply your key code where requested and click on the **Submit** button.

If you supplied the correct key code you will receive confirmation that your request is being processed. After your request is processed you will receive an e-mail confirmation.

**Note:** You cannot access the z/OS licensed books unless you have registered for access to them and received an e-mail confirmation informing you that your request has been processed.

To access the licensed books:

1. Log on to Resource Link using your Resource Link userid and password.
2. Click on **Library**.
3. Click on **zSeries**.
4. Click on **Software**.
5. Click on **z/OS**.
6. Access the licensed book by selecting the appropriate element.

## Using LookAt to Look Up Message Explanations

LookAt is an online facility that allows you to look up explanations for z/OS messages and system abends.

Using LookAt to find information is faster than a conventional search because LookAt goes directly to the explanation.

LookAt can be accessed from the Internet or from a TSO command line.

You can use LookAt on the Internet at:

<http://www.ibm.com/servers/eserver/zseries/zos/bkserv/lookat/lookat.html>

To use LookAt as a TSO command, LookAt must be installed on your host system. You can obtain the LookAt code for TSO from the LookAt Web site by clicking on **News and Help** or from the *z/OS Collection*, SK3T-4269 .

To find a message explanation from a TSO command line, simply enter: **lookat** *message-id* as in the following example:

```
lookat iec192i
```

This results in direct access to the message explanation for message IEC192I.

To find a message explanation from the LookAt Web site, simply enter the message ID. You can select the release if needed.

**Note:** Some messages have information in more than one book. For example, IEC192I has routing and descriptor codes listed in *z/OS MVS Routing and Descriptor Codes*. For such messages, LookAt prompts you to choose which book to open.

What You Need to Do to Write Servers . . . . .	4
Writing Access Method Drivers for MVSSERV . . . . .	5

This chapter introduces the TSO/E Enhanced Connectivity Facility, the server programs that you can write for it, and the MVSSERV command that manages TSO/E Enhanced Connectivity Facility sessions on MVS.

---

### Concepts of the TSO/E Enhanced Connectivity Facility

The TSO/E Enhanced Connectivity Facility provides a standard way for programs on different systems to share services.

With the TSO/E Enhanced Connectivity Facility, programs on properly-configured IBM Personal Computers (PCs) can obtain services from programs on IBM host computers running MVS. The PC programs issue *service requests* and the host programs issue *service replies*, which the TSO/E Enhanced Connectivity Facility passes between the systems.

The PC programs that issue service requests are called *requesters*, and the host programs that issue replies are called *servers*. Servers and requesters together form Enhanced Connectivity applications.

Because the TSO/E Enhanced Connectivity Facility passes the requests and replies, you can write servers and requesters without concern for communications protocols. The requester simply specifies the server's name, the request input, and a reply buffer. The server receives the input, performs the service, and provides the reply. The TSO/E Enhanced Connectivity Facility passes the requests and replies in a standard, easily-referenced control block.

Host servers can give PC users access to host computer data and resources such as printers and storage. This book explains how to write an MVS host server and includes a sample server that lets a PC requester process MVS data.

For information about PC hardware and software requirements, refer to *Enhanced Connectivity Facilities Introduction*.

---

### What is an MVS Server?

MVS *servers* are programs that provide MVS host services, through the TSO/E Enhanced Connectivity Facility, to *requester* programs on a properly configured IBM Personal Computer.

## What is an MVS Server?

MVS servers are made up of *service functions*. The servers themselves are defined in *initialization/termination programs*.

Figure 1 shows the logical organization of servers, their service functions, and an initialization/termination program.

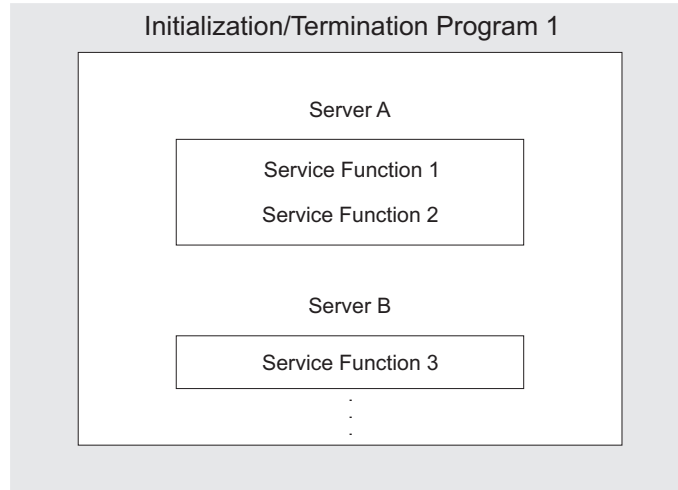

Figure 1. Logical Server Organization

## Service Functions

A service function is the part of a server that satisfies a particular service request.

A server can handle different service requests by having a service function for each request. Requests identify the service function as well as the server. The server receives the request and passes control to the requested service function. For details, see “Chapter 2. Designing and Writing a Server” on page 7.

Service functions can be related to the server in several ways: as subroutines of the server, as separate CSECTs, or as separate load modules.

## Initialization/Termination Programs

An initialization/termination program defines one or more servers and provides a common work environment and resources for them. In particular, an initialization/termination program does the following:

- Defines its servers to the TSO/E Enhanced Connectivity manager, MVSSERV, so MVSSERV can route service requests to the servers.
- Isolates servers in a single MVS subtask, thus protecting the main task (MVSSERV) or other subtasks from server failures.
- Obtains and releases resources such as data sets and storage for the servers.

Servers and their initialization/termination programs can be physically packaged as separate load modules or as separate CSECTs in the same load module. “Chapter 3. Designing and Writing a Server Initialization/Termination Program” on page 35 describes factors to consider when packaging servers and initialization/termination programs.

## What is MVSSERV?

MVSSERV is a TSO/E command processor that manages TSO/E Enhanced Connectivity sessions on the MVS host computer. Users issue MVSSERV on TSO/E to start an Enhanced Connectivity session. The users can then switch to PC mode and invoke requesters from an IBM PC that is running an Enhanced Connectivity program.

MVSSERV consists of a router and an interface to the servers. The server interface is called the *server-requester programming interface* (SRPI).

The router, through the SRPI, routes service requests to servers and routes service replies back to the requesters. Figure 2 shows the TSO/E Enhanced Connectivity environment during an MVSSERV session.

Figure 2. The MVSSERV Enhanced Connectivity Environment

## The SRPI

MVSSERV's server-requester programming interface (SRPI) resembles the CALL/RETURN interface of most high-level programming languages. Through the SRPI, MVSSERV gives the server control along with pointers to input, a buffer for output, and a return address. This interface allows you to write and use your own servers with MVSSERV.

Through the SRPI, MVSSERV calls servers and their initialization/termination programs for three phases of processing:

- Initialization -- setting up servers and their resources when MVSSERV begins, and defining the servers to MVSSERV.
- Handling service requests -- passing service requests to servers and sending back replies.
- Termination -- cleaning up servers and their resources when MVSSERV ends.

## What is MVSSERV?

### The CPRB Control Block

Service requests and replies pass through the SRPI in a control block called the *connectivity programming request block* (CPRB).

CPRBs have several purposes:

- The initialization/termination program uses a CPRB to define servers to MVSSERV.
- MVSSERV uses a CPRB to send service requests to the server, and to return the server's reply.
- Servers can send requests to other servers in a CPRB.

The CPRB contains service request data such as the following:

- The name of the requested server and the service function ID
- The lengths and addresses of buffers containing input
- The lengths and addresses of reply buffers

### The INITTERM Control Block

When MVSSERV begins and ends, it passes the INITTERM control block to the initialization/termination programs. INITTERM indicates whether the call is for initialization *or* termination, and includes other input that the program needs.

### The Sequence of Events in an MVSSERV Session

Figure 3 shows the sequence of events in an MVSSERV session.

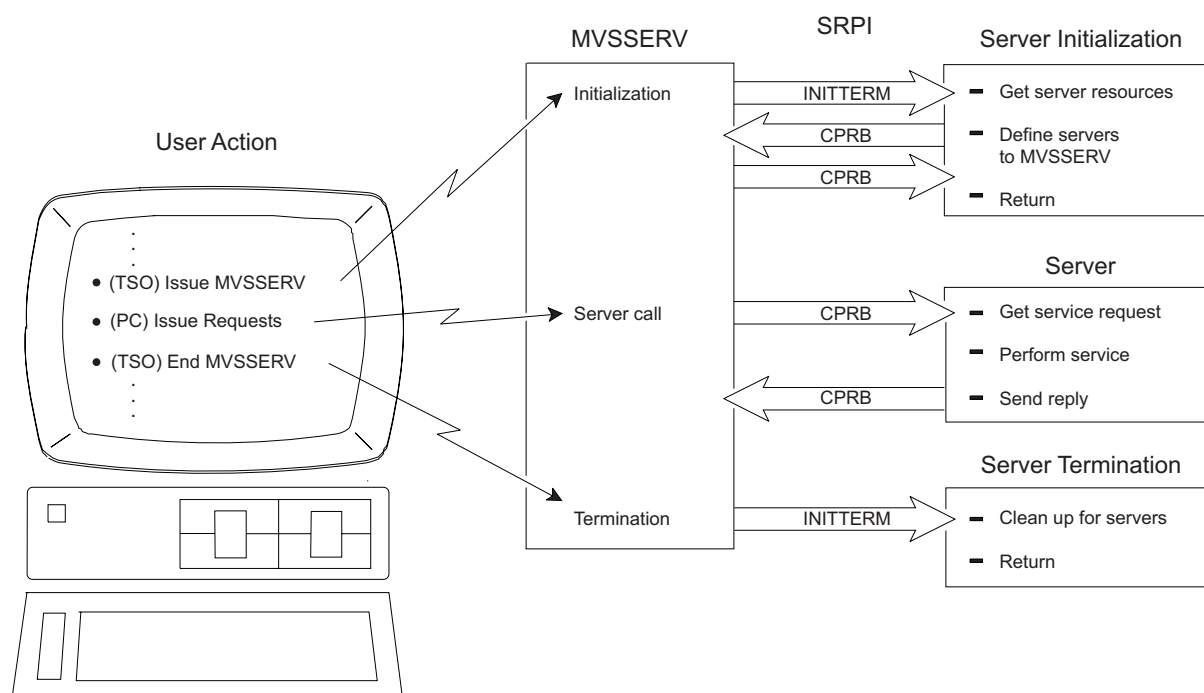

Figure 3. Events in an MVSSERV Session

## What You Need to Do to Write Servers

The following is an overview of the steps you need to follow when writing servers for MVSSERV. Subsequent chapters of the book give further details.

## What You Need to Do to Write Servers

1. Select or create a load module data set to contain the executable code for the server and initialization/termination program. If the server and initialization/termination program are in different load modules, the initialization/termination program must load the server (see “Chapter 3. Designing and Writing a Server Initialization/Termination Program” on page 35 for details).
2. Write the server (see “Chapter 2. Designing and Writing a Server” on page 7).
  - The server must:
    - Access the service request input in the CPRB.
    - Call the requested service function.
    - Perform the service, calling other servers if necessary.
    - Indicate the reply length in the CPRB.
    - Set the return code in register 15.
    - Return control to MVSSERV.
    - Provide recovery (optional).
  - Compile or assemble the server and link it to a load module.
3. Write an initialization/termination program (see “Chapter 3. Designing and Writing a Server Initialization/Termination Program” on page 35).
  - For initialization, the program must:
    - Load the server (if necessary).
    - Obtain resources (if necessary).
    - Define the server to MVSSERV and pass a parameter list (parmlist) pointing to any resources.
4. For termination, the program must:
  - Free any resources.
  - Delete the server (if loaded).
  - Compile or assemble the initialization/termination program and link it to a load module.
5. Install the server and initialization/termination program (see “Chapter 5. Installing Programs and Data Sets for Use with MVSSERV” on page 59).
  - Install the programs in a STEPLIB or system library.
  - Define the initialization/termination program to MVSSERV in the input parameter data set.
  - Allocate diagnosis data sets (optional):
    - Trace data set
    - Dump data set
    - Dump suppression data set
6. Invoke MVSSERV to test your server (see “Chapter 6. Testing and Diagnosis” on page 65).

---

## Writing Access Method Drivers for MVSSERV

MVSSERV includes programs called access method drivers (AMDs), which manage Host-to-PC communications across certain hardware connections. Specifically, the MVSSERV AMDs communicate with PCs that have Distributed Function Terminal (DFT) and Control Unit Terminal (CUT) mode attachment to the host through the IBM 3174 or 3274 control unit. In addition, MVSSERV allows installations to write and install their own AMDs to manage other communication methods. “Chapter 4. Writing an Access Method Driver” on page 53 describes MVSSERV’s AMD interface and special considerations for writing your own AMDs.

Issuing Messages. . . . .	12
The Server Recovery Routine . . . . .	12
Compiling or Assembling a Server. . . . .	12
Sample Servers . . . . .	12

This chapter describes the steps to follow when designing and writing servers.

---

### Server Design

Servers provide MVS services, data, and resources to requester programs. Therefore, before you write a server, you need to define what output it will provide, and what requester input it will receive.

Servers and requesters work in pairs. Each service request must name the corresponding server and service function and must include any input that the server needs. The server must use the input and provide output that the requester can use.

For information about writing requesters, refer to *IBM Programmer's Guide to the Server-Requester Programming Interface for the IBM Personal Computer and the IBM 3270 PC*.

---

### Steps for Designing a Server

Follow these steps when designing a server:

1. Decide what service request (or requests) your server will handle. If your server handles more than one service request, your server needs a service function for each request. The service functions can be:
  - Server subroutines
  - Server CSECTs
  - Load modules that are separate from the server

If a service function fails, all other service functions of the same server are disabled. For recovery purposes, you might want to handle unrelated requests in separate servers rather than in functions of the same server. You could then isolate the servers by defining them in different initialization/termination programs (for details, see "Steps for Designing an Initialization/Termination Program" on page 36).

2. Decide whether the server should use 24- or 31-bit addressing. Servers can execute in AMODE 24 or 31, and in RMODE 24 or ANY.
3. Select a name for the server. Names can have up to eight characters, including the characters A-Z, 0-9, @, #, and \$. The first character cannot be 0-9.

## Writing a Server

Your server must follow certain rules to receive service requests and reply to them successfully. The rules apply to using the connectivity programming request block (CPRB).

### Using the CPRB

To respond to a service request, the server must:

- Receive the service request input in the CPRB
- Perform the service
- Send a service reply in the CPRB

Figure 4 shows the process for handling service requests.

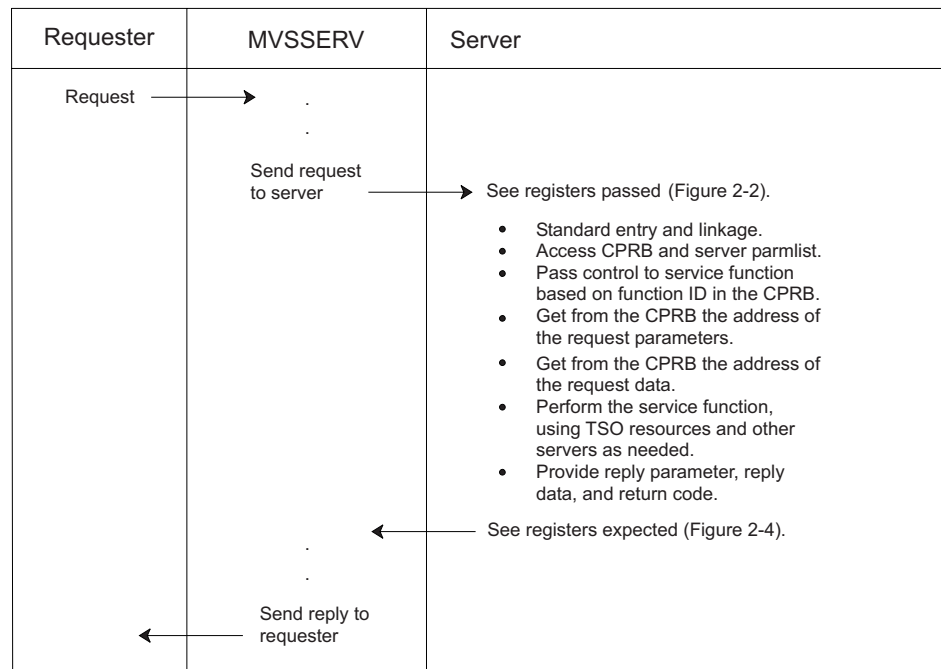

Figure 4. Overview of Service Request Handling

### Receiving the Service Request

MVSSERV passes control to the server in key 8, problem program state, with the register contents shown in Figure 5 on page 9.

Register 1 points to a three-word area that contains addresses of the CPRB, the connectivity environment descriptor (CED), and a parameter list (parmlist) from the server initialization/termination program. Of the three:

- The CPRB contains the service request.
- The CED is for MVSSERV use only. (If the server issues the DEFSEV, SENDREQ, or CHSTRACE macros, it must pass the CED address.)
- The server parmlist can point to resources such as data sets for the server to use. (For details about creating the server parmlist, see “Chapter 3. Designing and Writing a Server Initialization/Termination Program” on page 35.)

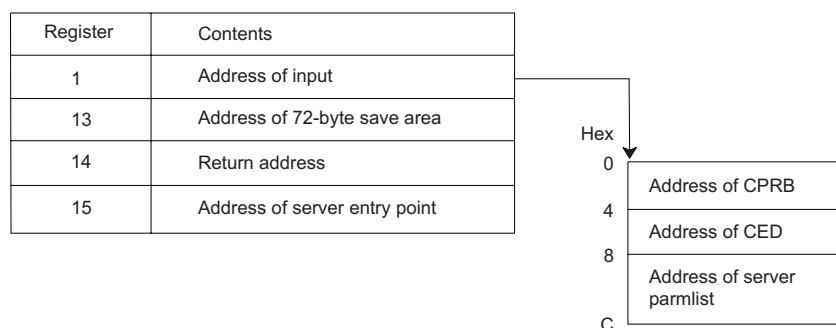

Figure 5. Registers Passed to the Server

## Mapping to the CPRB Fields

Your server can use the CHSDCPRB mapping macro to access the fields of the CPRB. For details, see “CHSDCPRB Macro” on page 69.

Table 1 shows the CPRB with the fields that pertain to the server.

## The Receive Request CPRB (Entry to Server)

Table 1. CPRB Control Block on Entry to Server

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	1	CRBF1	The control block's version number (first four bits) and modification level number (last four bits).
1(1)	2		Reserved
3(3)	1	CRBF4	The type of request. X'01' indicates a service request. (X'03' indicates a define server (DEFSERV) request.)
4(4)	4	CRBCPRB	Control block identifier (character string 'CPRB').
8(8)	8		Reserved
16(10)	8	CRBSNAME	The name of the requested server.
24(18)	2		Reserved
26(1A)	2	CRBFID <sup>1</sup>	The ID of the requested service function (1-99)
28(1C)	12		Reserved
40(28)	4	CRBRQDLN <sup>1</sup>	The length of the request data.
44(2C)	4	CRBRQDAT <sup>1</sup>	The address of the request data.
48(30)	4	CRBRPDLN <sup>2</sup>	The length of the reply data (maximum length allowed by the requester).
52(34)	4	CRBRPDAT <sup>3</sup>	The address of the buffer for reply data.
56(38)	4	CRBRQPLN <sup>1</sup>	The length of the request parameters.
60(3C)	4	CRBRQPRM <sup>1</sup>	The address of the request parameters.
64(40)	4	CRBRPPLN <sup>2</sup>	The length of the reply parameters (maximum length allowed by the requester).
68(44)	4	CRBRPPRM <sup>3</sup>	The address of the buffer for reply parameters.
72(48)	40		Reserved

Notes:

## Writing a Server

- 1** **Request** field. Use but do not alter.
- 2** **Request/Reply** field. The requester initializes these fields. The server may modify the contents of these fields.
- 3** **Address of Reply** field. Use but do not alter. The server may return information in a buffer located at this address. Do not return more information than will fit in the buffer (as indicated in the associated length field).

Do not modify any fields other than those marked with a **2**.

## Performing the Service

To perform a service, the server can:

- Use any MVS facilities available to a problem program.
- Define other servers to MVSSERV, using the DEFSEV macro.
- Send requests, using the SENDREQ macro, to other servers that have previously been defined in the current MVSSERV session.
- Issue messages to the terminal, to the MVSSERV trace data set, or to both, using the CHSTRACE macro.

### Using Request and Reply buffers

Servers and requesters can use request and reply buffers to pass any agreed-upon information. The CPRB lets you specify separate buffers for data and parameters, but their use is unrestricted. For example, an application might use parameter buffers to pass instructions to the server and data buffers to pass the results. MVSSERV does not verify or modify the buffer contents.

To share data and parameters with a PC requester, the MVS server might need to convert request data and parameters from ASCII to EBCDIC, and convert reply data and parameters from EBCDIC to ASCII. The sample servers in Figure 7 on page 23 and Figure 8 on page 29 demonstrate how to perform such data conversion.

## Sending the Service Reply

If the server can perform the requested service function, the server should:

- Move reply data, if any, to the reply data buffer pointed to by CPRB field CRBRPDAT.
- Move reply parameters, if any, to the reply parameter buffer pointed to by CPRB field CRBRPPRM.
- Set the actual reply data length (number of bytes) in CPRB field CRBRPDLN (the actual length must be less than or equal to the reply data length passed from the requester).
- Set the actual reply parameter length (number of bytes) in CPRB field CRBRPPLN (the actual length must be less than or equal to the reply parameter length passed from the requester).

Whether or not the server can perform the requested service function, it must:

- Put the return code expected by the requester in register 15.
- Return the reply CPRB to the requester (branch to the return address that was in register 14 on entry to the server).

The registers should have the following contents when the server ends:

**Register 13** Register Address of 72-byte save area

**Register 14**     Register Return address

**Register 15**     Register Server return code

Table 2 shows the CPRB fields that the server uses in its reply.

### The Send Reply CPRB (Exit from Server)

*Table 2. CPRB Control Block on Exit from the Server*

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	48		Reserved
48(30)	4	CRBRPDLN <sup>1</sup>	Specify the actual length of the reply data.
52(34)	12		Reserved
64(40)	4	CRBRPPLN <sup>1</sup>	Specify the actual length of the reply parameters.
68(44)	44		Reserved

*Note:*

- 1**     The actual length cannot exceed the initial value (maximum allowed by the requester).

## Sending a Service Request

In the process of handling a service request, a server can issue its own service requests to another MVS server defined in the same MVSSERV session. A server can use the results of its request in its reply.

To send a service request from a server, use the CHSDCPRB macro to create a CPRB and the SENDREQ macro to initialize and send the CPRB. For details, see “SENDREQ Macro” on page 73. The SENDREQ macro sends a service request to another server in a CPRB identical to the one shown in Table 1 on page 9.

## Receiving a Service Reply

On return from the SENDREQ macro, an updated CPRB and reply buffers are returned, indicating the status of the requested service. Table 3 shows the CPRB on return from issuing a service request.

### The Receive Reply CPRB (Entry to Server)

*Table 3. CPRB Control Block with Reply from Another Server*

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	8		Reserved
8(8)	4	CRBSRTNC <sup>1</sup>	The server return code from Register 15. (Filled in by MVSSERV.)
12(C)	4	CRBCRTNC <sup>2</sup>	The return code from MVSSERV. For a list of return codes, see Chapter 8. MVSSERV Return Codes.
16(10)	32		Reserved
48(30)	4	CRBRPDLN <sup>3</sup>	The length of the reply data.
52(34)	12		Reserved
64(40)	4	CRBRPPLN <sup>3</sup>	The length of the reply parameters.
68(44)	44		Reserved

## Writing a Server

*Notes:*

- 1** Check for a return code from the server.
- 2** Check for a return code from MVSSERV.
- 3** Use to obtain reply data and parameters from their buffers.

## Issuing Messages

Your servers can issue messages to the terminal, to the MVSSERV trace data set, or to both. To issue a message and specify its destination, use the CHSTRACE macro.

For details of the CHSTRACE macro, see “Chapter 7. Macro Syntax and Parameters” on page 69. For information about the MVSSERV trace data set, see “Trace Data Set” on page 61.

## The Server Recovery Routine

Servers can have their own recovery routines. If a server fails and does not recover, MVSSERV traps the error, provides a dump, and prevents that server or any other servers defined by the same initialization/termination program from processing further requests during that MVSSERV session.

To establish a recovery routine, servers must issue the ESTAE macro. The server recovery routine should do the following:

- Record pertinent diagnostic information in the SDWA and VRA, such as the caller, the current module in control, and the input parameters.
- Optionally, specify a dump (if not, MVSSERV provides one).
- If the failure is recoverable, set return parameters specifying that a retry is to be made. The retry routine must return control to MVSSERV with the server's return code.
- If the failure is not recoverable, percolate to MVSSERV.

For more information about using the ESTAE macro and recovery routines, refer to *z/OS MVS Programming: Authorized Assembler Services Reference ALE-DYN*.

For an example of a server recovery routine, see Figure 6 on page 14.

---

## Compiling or Assembling a Server

After writing a server, you must compile or assemble it and link-edit it. For information about preparing and running a program in TSO/E, refer to *z/OS TSO/E Programming Guide*.

---

## Sample Servers

The sample server in Figure 6 corresponds to the sample assembler requester in the *IBM Programmer's Guide to the Server-Requester Programming Interface for the IBM Personal Computer and the IBM 3270 PC*. The server, IBMABASE, has two service functions:

- Function 1 sends a request to server IBMABAS1 in Figure 7 to:
  - Retrieve a record from a customer records data set on MVS
  - Translate the record into ASCII
  - Send the record to the requester for processing
- Function 2 sends a request to server IBMABAS2 in Figure 8 to:

## Sample Servers

- Receive a record with a positive balance from the requester
- Translate the record back into EBCDIC
- Put the record into an accounts receivable data set on MVS

The initialization/termination program for these servers is shown in Figure 14 on page 43.

The recovery routine in IBMABASE covers errors in the server itself. Errors in the called servers (IBMABAS1 and IBMABAS2) are handled by MVSSERV's recovery routine, which informs IBMABASE if they fail.

Sample Initialization/Termination Program . . . . .	42

This chapter describes the steps to follow when designing and writing server initialization/termination programs.

---

### Program Design

The initialization/termination programs are logically grouped in separate subtasks. They define one or more servers to MVSSERV, and optionally load the servers and provide resources for them. When MVSSERV ends, it re-invokes your initialization/termination programs to free any server resources and terminate the servers.

Figure 9 shows the position of initialization/termination programs in the logical MVSSERV task structure.

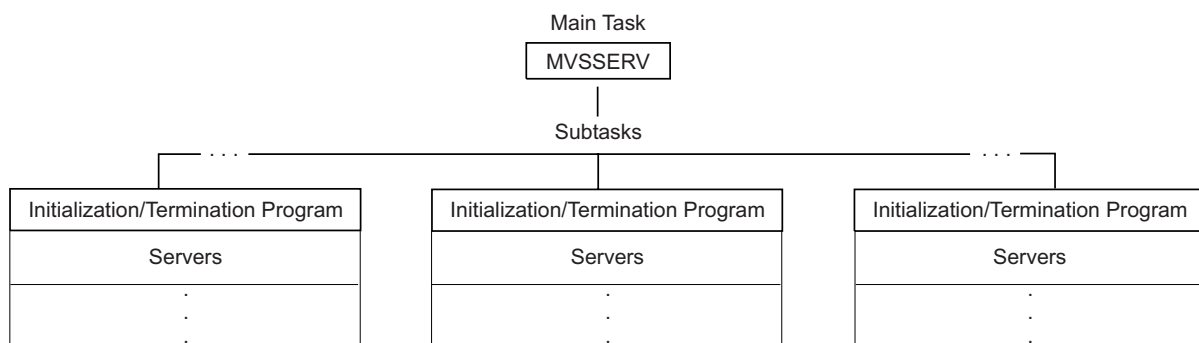

Figure 9. MVSSERV Logical Task Structure

When you design an initialization/termination program, you need to consider what servers it will define, what resources the servers require, and how to package the initialization/termination program in relation to the servers.

### Steps for Designing an Initialization/Termination Program

Follow these steps when designing an initialization/termination program:

1. Decide what servers the initialization/termination program will define. The main considerations are server resources and recovery.
  - Resources -- The initialization/termination program can obtain and release resources such as storage and data sets for its servers. If servers share resources, you can increase their efficiency by having a single initialization/termination program define the servers and obtain and release the resources for them.
  - Recovery -- If a server fails and cannot recover, MVSSERV calls the server's initialization/termination program to terminate all the servers it defined. Therefore, you might want to define related servers in the same initialization/termination program, and define unrelated servers in different initialization/termination programs.
2. Decide how to package the initialization/termination program in relation to the servers.

You can package servers and their initialization/termination program as CSECTs of the same load module or as different load modules. The main consideration is server loading:

  - If you do not want the initialization/termination program to load the server, place the initialization/termination program and server in the *same* load module. The initialization/termination program can use a constant server address to define the server to MVSSERV.
  - If you want the initialization/termination program to load the server, place the initialization/termination program and server in *different* load modules. The initialization/termination program can get the server address from the LOAD macro to define the server to MVSSERV.
3. Decide whether the initialization/termination program server should use 24- or 31-bit addressing. Initialization/termination programs can execute in AMODE 24 or 31, and RMODE 24 or ANY.
4. Select a name for the initialization/termination program. Names can have up to eight characters, including the characters A-Z, 0-9, @, #, and \$. The first character cannot be 0-9.
5. Put the name of the initialization/termination program in the input parameter data set (see "Chapter 5. Installing Programs and Data Sets for Use with MVSSERV" on page 59).

---

### Writing an Initialization/Termination Program

Figure 10 on page 37 gives an overview of an initialization/termination program's processing.

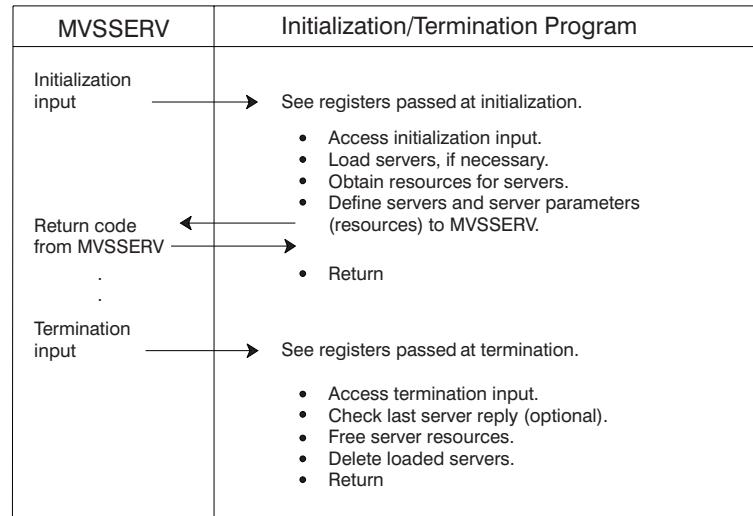

Figure 10. Overview of an Initialization/Termination Program's Processing

## Initialization

When MVSSERV receives control, it invokes the server initialization/termination programs in separate subtasks. MVSSERV gets the names of the initialization/termination programs from the input parameter data set described in "Chapter 5. Installing Programs and Data Sets for Use with MVSSERV" on page 59.

## Input to the Initialization/Termination Program

Figure 11 and Table 4 show the input that MVSSERV makes available to the initialization/termination programs.

When MVSSERV gets control, it invokes your server initialization/termination programs in problem program state, key 8.

As shown in Figure 11, register 1 points to a two-word area. The first word contains the address of the INITTERM control block; the second word contains the address of the CED (connectivity environment descriptor). Of the two:

- INITTERM indicates whether the call is for initialization or termination.
- The CED is for MVSSERV use only. (If the program issues the DEFSERV, SENDREQ, or CHSTRACE macros, it must pass the CED address.)

You can use the INITTERM mapping macro to obtain input from the INITTERM

Figure 11. Registers Passed at Initialization

control block. For details, see "INITTERM Macro" on page 70. Table 4 shows the INITTERM control block with the initialization input.

## Initialization

Table 4. INITTERM Control Block with Initialization Input

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	4	INTINIT <sup>1</sup>	Initialization or termination indicator. X'00000000' indicates the call is for initialization. X'00000001' indicates termination.
4(4)	4	INTWALEN <sup>2</sup>	Work area length. Specify the length of a work area that the program can use at termination time.
8(8)	4	INTWAPTR <sup>2</sup>	Work area address. Specify the address of a work area that the program can use at termination time.
12(C)	16	INTENVRN	Reserved
28(1C)	4		Address of the TSO/E CPPL (command processor parameter list). The CPPL is for system use only; its address must be in register 1 if a server or initialization/termination program invokes a TSO/E command processor or uses TSO/E services such as SCAN or PARSE. For more information about the CPPL, see <i>z/OS TSO/E Programming Guide</i> .
32(20)	4		Reserved

Notes:

- <sup>1</sup> Check for initialization or termination indicator.
- <sup>2</sup> Specify a work area (optional).

## Loading the Servers

If the servers are not in the same load module as their initialization/termination program, the initialization/termination program must load the servers.

The following assembler language example shows how an initialization/termination program can load a server that is not in the same load module.

```
LOAD EP=server name      Load the server
LR   5,0                  Get server address from LOAD macro
                                for use in the DEFSEV macro
                                :
                                :
```

## Obtaining Resources

An initialization/termination program can obtain any resources that its servers require or share. For example, the initialization/termination program can:

- Open data sets that the servers need.
- Obtain storage, such as a work area to be shared among the servers, by issuing the GETMAIN macro.

The initialization/termination program makes resources available to the server by pointing to them in a server parameter list (parmlist) as part of the server definition process. When MVSSERV passes a service request to the server, it passes the server parmlist list as well.

## Defining a Server

The initialization/termination program must define its servers to MVSSERV. The definition must include the names and addresses of the servers and the addresses of any parameter lists to be passed to the servers along with service requests. MVSSERV makes a table of the names and addresses; the MVSSERV router obtains the addresses of requested servers from the table.

You can define servers using the DEFSEVER macro. The DEFSEVER macro fills in fields of a connectivity programming request block (CPRB) that does the following:

- Defines the server to MVSSERV.
- Specifies a parmlist for the server.

For details about the DEFSEVER macro, see “DEFSEVER Macro” on page 71.

### Results of the DEFSEVER Macro

The DEFSEVER macro fills in fields of a CPRB that MVSSERV uses to identify the server name with the server's address and parmlist. The CPRB and its significant fields are shown in Table 5.

### The DEFSEVER Request CPRB

Table 5. CPRB Control Block Used to Define a Server

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	1	CRBF1	The control block's version number (first four bits) and modification level number (last four bits).
1(1)	2		Reserved
3(3)	1	CRBF4	The type of request (X'03' indicates a Define Server request).
4(4)	4	CRBCPRB	The value of C'CPRB'.
8(8)	8		Reserved
16(10)	8	CRBSNAME	The server name specified in the DEFSEVER parameter SERVNAME.
24(18)	32		Reserved
56(38)	4	CRBRQPLN	The value X'0003', indicating the length of the define server parameter area.
60(3C)	4	CRBRQPRM	The address of the define server parameter area.
64(40)	48		Reserved

**Note:** All fields shown are set by the DEFSEVER macro.

### The Define Server Parameter Area

The field CRBRQPRM of the DEFSEVER CPRB points to the *define server parameter area*. This area, created by the DEFSEVER MACRO, points to the following:

- The server entry point.
- The server parmlist - resources passed to the server when it is called.

Figure 12 shows the format of the define server parameter area.

## Initialization

Figure 12. The Define Server Parameter Area

## Sending a Service Request

An initialization/termination program can send service requests to servers that it defines. For example, at termination an initialization/termination program can check the status of the last reply (see Table 6 on page 41) sent to the PC. If the last reply had an unsuccessful return code caused by a communication failure, the initialization/termination program could send a request to the server that issued the reply, directing the server to cancel its last service.

To send a service request to a server, use the CHSDCPRB macro to create a CPRB and the SENDREQ macro to initialize and send the CPRB. For details, see “SENDREQ Macro” on page 73. The SENDREQ macro sends a service request to another server in a CPRB identical to the one shown in Table 1 on page 9.

## Receiving a Service Reply

On return from the SENDREQ macro, an updated CPRB and reply buffers are returned, indicating the status of the requested service. Table 3 on page 11 shows the CPRB on return from issuing a service request.

## Issuing Messages

Initialization/termination programs can issue messages to the terminal, to the MVSSERV trace data set, or to both. To issue a message and specify its destination, use the CHSTRACE macro. For details, see “CHSTRACE Macro” on page 76. For information about the MVSSERV trace data set, see “Trace Data Set” on page 61.

## Recovery

Like the server, the initialization/termination program can have its own recovery routine. If the initialization/termination program fails and does not recover, MVSSERV traps the error and prevents all the servers in the subtask from processing any more requests.

If the initialization/termination program provides recovery, it must use the ESTAE 0 option to delete its recovery environment before returning control to MVSSERV after initialization and after termination.

For more information about using the ESTAE macro and recovery routines, refer to *z/OS MVS Programming: Authorized Assembler Services Reference ENF-IXG*.

## Ending Initialization

When the initialization/termination program is finished with initialization, it must return control to MVSSERV with a return code of 0 (successful) or 4 (unsuccessful)

in register 15. If the return code is 4, MVSSERV marks all the servers in the subtask as unavailable, preventing them from processing requests, and immediately invokes the initialization/termination program for termination.

## Termination

Before MVSSERV ends, it calls the initialization/termination program again to delete the servers (if loaded) and free any resources obtained for them. The termination input to the initialization/termination program is shown in Figure 13 and Table 6, with the significant fields indicated.

Figure 13. Registers Passed at Termination

Table 6. INITTERM Control Block with Termination Input

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	4	INTINIT <sup>1</sup>	Initialization or termination indicator. X'00000001' indicates that the call is for termination.
4(4)	4	INTWALEN	Work area length. The length of a work area, if any, specified at initialization.
8(8)	4	INTWAPTR	Work area address. The address of a work area, if any, specified at initialization.
12(C)	8	INTSNAME <sup>2</sup>	Name of last server to send a reply. If the initialization/termination program defined this server and the last reply was not received successfully (see INTRSN), the initialization/termination program may take appropriate action; for example, cancelling the last service performed.
20(14)	4	INTRSN <sup>3</sup>	Return code for last reply. Contains one of the following return codes: <div> <div>0(0)</div> <div>4(4)</div> <div>8(8)</div> <div>10(A)</div> </div> Processing was successful. The last reply <i>may not</i> have been successfully received by the requester. The last reply was not successfully received by the requester. The last reply CPRB from the server was not valid.
24(18)	4		Reserved
28(1C)	4	INTENVRN	CPPL address (see Table 4 on page 38)
32(20)	4		Reserved

Notes:

## Termination

- 1** Check for initialization or termination.
- 2** Check the name of the last server to send a reply (optional).
- 3** If the last server was defined by the initialization/termination program, check the status of the last reply (optional). If the last reply had an unsuccessful return code, the initialization/termination program could send a request to the server that issued the reply, directing the server to cancel its last service.

## Freeing Resources

The initialization/termination program must release any resources that it obtained. For example, the program must:

- Use the FREEMAIN macro to free any storage that it obtained by GETMAIN during initialization.
- Close any data sets that it opened.

## Deleting the Servers

The initialization/termination program must delete any servers that it loaded. The following assembler language example shows how to delete a server.

```
DELETE EP=server name          Delete the server
      :
```

When finished, the initialization/termination program must return control to MVSSERV with a return code of 0 (successful) or 4 (unsuccessful) in register 15.

---

## Compiling or Assembling an Initialization/Termination Program

After writing an initialization/termination program, you must compile or assemble it and link-edit it. For information about preparing and running a program in TSO/E, see *z/OS TSO/E Programming Guide*.

---

## Sample Initialization/Termination Program

The initialization/termination program in Figure 14 corresponds to the sample server in Figure 6 on page 14. The initialization/termination program does the following:

- Loads the server.
- Issues the DEFSERV macro.
- Cleans up at termination.

## Sample Initialization/Termination Program

Sending a Service Request . . . . .	55
Receiving a Service Reply. . . . .	55
Issuing Messages. . . . .	56
Sample Access Method Driver . . . . .	57

This chapter describes the role of MVSSERV access method drivers and MVSSERV's access method driver interface.

---

### What is an Access Method Driver?

Access method drivers (AMDs) are programs that provide the communications link between MVSSERV and a PC. Access method drivers on the host and PC work in pairs, passing data between them in a format appropriate to the mode of PC-to-Host attachment. At the host, MVSSERV's access method driver converts requests into CPRBs, sends them to servers, and converts reply CPRBs back into the proper communications format for transmission to the PC.

MVSSERV provides access method drivers that manage communications with PCs attached to the host through an IBM 3174 or 3274 control unit in:

- Distributed Function Terminal (DFT) mode
- Control Unit Terminal (CUT) mode

MVSSERV also provides an AMD interface that lets you write and install other access method drivers to support other modes of attachment. Figure 15 shows the position of the AMD interface in the MVSSERV environment.

## What is an Access Method Driver?

Figure 15. The MVSSERV Enhanced Connectivity Environment

## Using the AMD Interface

The purpose of the AMD interface is to let installations write and install access method drivers to support different modes of PC-to-host attachment. If an access method driver is properly installed on MVS and defined to MVSSERV, MVSSERV invokes the access method driver. Then MVSSERV routes service requests from the access method driver to the servers, and routes service replies back to the access method driver. An access method driver on the host must have a counterpart on the PC; the access method drivers are responsible for ensuring that requests from the PC reach MVSSERV in the proper format, and that replies from MVSSERV reach the PC properly.

## Writing an Access Method Driver

You can write access method drivers to support different modes of PC-to-host attachment. An access method driver must do the following:

- Receive requests from the PC
- Use the SENDREQ macro to send the requests to servers
- Receive the server replies
- Send the replies to the requester in the appropriate form.
- At termination, free any resources and notify the PC counterpart.

### Installing and Defining an Access Method Driver

To make an access method driver available to MVSSERV, you must install the access method driver on MVS and define it in MVSSERV's input parameter data set. See Chapter 5. Installing Programs and Data Sets for Use with MVSSERV for information about installing access method drivers and defining them in the MVSSERV input parameter data set.

### AMD Invocation

When MVSSERV finds an access method driver defined in the input parameter data set, MVSSERV loads and invokes it. MVSSERV passes a single parameter to the access method driver: the address of a Connectivity Environment Descriptor (CED), as shown in Figure 16.

Figure 16. MVSSERV Input to an Access Method Driver

The CED address is for MVSSERV use only; to issue the SENDREQ or CHSTRACE macros, the access method driver must pass the CED address in the macro.

## Considerations for Writing Access Method Drivers

Installation-written access method drivers must:

- Run AMODE 31 and RMODE ANY.
- Provide their own recovery routines.
- Display their own screens or logos. MVSSERV does not display its logo when a user-defined access method driver is running.

In addition, access method drivers may not issue the DEFSEVR macro to define servers. In order for MVSSERV to route requests to servers, the servers must be defined to MVSSERV by initialization/termination programs or by other servers.

## Sending a Service Request

The primary function of an access method driver is to receive service requests, send the service requests to servers, receive service replies from the servers, and send the service replies back to the requester. Service requests must be sent to servers in a CPRB control block.

To send a service request, you can use the CHSDCPRB macro to create a CPRB and the SENDREQ macro to initialize the CPRB with the request and send it to the server. For details, see “SENDREQ Macro” on page 73. The SENDREQ macro sends the service request in a CPRB as shown in Table 1 on page 9.

## Receiving a Service Reply

On return from a service request, an updated CPRB and reply buffers are returned, indicating the results of the requested service. ( Table 3 on page 11 shows the CPRB on return from a service request.) The access method driver on the host must convert the reply information into the appropriate format and send the information to its PC counterpart. The PC counterpart must convert the information back into a CPRB and send it to the requester. For complete information about the format of the CPRB that the requester expects, see the *IBM Programmer's Guide to the Server-Requester Programming Interface for the IBM Personal Computer and the IBM 3270 PC*.

## Considerations for Writing Access Method Drivers

### Issuing Messages

An access method driver can issue messages to the terminal, to the MVSSERV trace data set, or to both. To issue a message and specify its destination, use the CHSTRACE macro. For details, see “CHSTRACE Macro” on page 76. For information about the MVSSERV trace data set, see “Trace Data Set” on page 61.

## Sample Access Method Driver

The following sample is provided to illustrate use of the AMD interface. The sample does not represent a functional access method driver.

```

## Chapter 5. Installing Programs and Data Sets for Use with MVSSERV

Installing a Program . . . . .	59
In a STEPLIB . . . . .	59
In a System Library . . . . .	59
Using the Input Parameter Data Set . . . . .	60
Allocating the Input Parameter Data Set . . . . .	60
Initializing the Input Parameter Data Set . . . . .	60
Additional MVSSERV Data Sets . . . . .	61
Trace Data Set . . . . .	61
Dump Data Set. . . . .	61
Dump Suppression Data Set . . . . .	62

This chapter describes how to install servers, initialization/termination programs, and access method drivers for use with MVSSERV. This chapter uses the term *program* to collectively refer to the above programs.

After a program has been written, compiled or assembled, and link-edited, you must install the program to make it available to users and to MVSSERV.

Installation is a two-step process. The steps are:

1. Install the program in a library.
2. Use the input parameter data set to identify initialization/termination programs and access method drivers.

---

### Installing a Program

You can install a program in one of two ways:

- In a STEPLIB
- In a system library.

#### In a STEPLIB

You can install a program in a STEPLIB that is allocated in a user's logon procedure. This method of installation lets you restrict the program to specific users, and is recommended when testing a new program.

To allocate a STEPLIB to a user, add the following JCL in the user's logon procedure:

```
//STEPLIB DD DSN=data_set_name,DISP=SHR
```

#### In a System Library

To make a program available to all system users, copy it to a member of a system library. The system library can be one that is defined in the linklist concatenation, such as SYS1.LINKLIB, or it can be SYS1.LPALIB, which is allocated at IPL and therefore always available.

Programs in system libraries should be (and programs in SYS1.LPALIB *must* be) reentrant--that is, they must use dynamic storage to allow multiple and concurrent executions of the program. The sample programs in this book are reentrant, and macro descriptions in "Chapter 7. Macro Syntax and Parameters" on page 69 indicate steps to take to make a program reentrant.

### Using the Input Parameter Data Set

Before issuing the MVSSERV command, you must name, in the input parameter data set, your initialization/termination programs and optionally, any access method driver. From this input, MVSSERV invokes the access method driver, if any, to manage communications, and the initialization/termination programs, which define the servers to MVSSERV.

### Allocating the Input Parameter Data Set

The input parameter data set must have the following characteristics:

- ddname -- CHSPARM
- logical record length -- 80
- format -- fixed or fixed block

You can create the input parameter data set with the following command:

```
ALLOCATE FILE(CHSPARM) DA('data_set_name') NEW LRECL(80) RECFM(F)
```

To make the input parameter data set available to an MVSSERV user, allocate the existing data set in the user's logon procedure, or in a CLIST, REXX exec, or ISPF dialog that issues MVSSERV for the user.

- In a logon procedure, you can use the following JCL:

```
//CHSPARM DD DSN=data_set_name,DISP=SHR
```

- In a CLIST, REXX exec, or ISPF dialog, you can use the following command:

```
ALLOCATE FILE(CHSPARM) DA('data_set_name') SHR
```

Be sure that the user has security authorization to access the input parameter data set.

### Initializing the Input Parameter Data Set

Each record of the input parameter data set must contain the name of an initialization/termination program or an access method driver, starting in column 1. The name can have up to eight characters, including the characters A-Z, 0-9, @, #, and \$. The first character cannot be 0-9.

To distinguish access method drivers from initialization/termination programs, include the TYPE keyword in the input record anywhere between columns 9 and 72. An access method driver must be followed by the keyword TYPE(A); initialization/termination programs can be followed by the keyword TYPE(I) or by no keyword.

For example, in the following lines from an input parameter data set, the first two programs are initialization/termination programs and the third (AMDPROG) is an access method driver.

```
-----1-----2-----3-----4-----5---
```

```
INTPROG1  
INTPROG2  TYPE(I)  
AMDPROG   TYPE(A)
```

MVSSERV invokes all initialization/termination programs it finds in the input parameter data set, but invokes only the first access method driver it finds, ignoring any other TYPE(A) programs.

## Additional MVSSERV Data Sets

In addition to the input parameter data set, you can allocate optional data sets to contain MVSSERV diagnosis information. These diagnostic data sets can also be allocated in a user's logon procedure, in a CLIST, REXX exec, or ISPF dialog that invokes MVSSERV, or in line mode TSO/E. The diagnostic data sets and their functions are as follows:

- Trace data set -- receives trace data and messages
- Dump data set -- receives system dump data
- Dump suppression data set -- lets you specify abend codes for which you do not want dumps to be taken

### Trace Data Set

You can specify a data set to receive trace data from an MVSSERV session, as well as messages issued by the CHSTRACE macro. For messages and data to be received in the trace data set, MVSSERV must be invoked with the TRACE or IOTRACE option. The level of trace data from MVSSERV varies with the option used:

- TRACE -- records events in the MVSSERV session, such as requests for servers, and MVSSERV errors.
- IOTRACE -- records the TRACE information and communications with the PC, including data transmissions and the contents of the CPRB.

#### Allocating the Trace Data Set

The trace data set must have the following characteristics:

- ddname -- CHSTRACE
- logical record length -- 80
- format -- fixed or fixed block

You can create the trace data set with the following command:

```
ALLOCATE FILE(CHSTRACE) DA('data_set_name') NEW LRECL(80) RECFM(F)
```

To make the trace data set available to an MVSSERV user, allocate the existing data set in the user's logon procedure, or in a CLIST, REXX exec, or ISPF dialog that issues MVSSERV for the user. Users must have their own trace data sets.

- In a logon procedure, you can use the following JCL:  

```
//CHSTRACE DD DSN=data_set_name,DISP=OLD
```
- In a CLIST, REXX exec, or ISPF dialog, you can use the following command:  

```
ALLOCATE FILE(CHSTRACE) DA('data_set_name') OLD
```

For more information about the MVSSERV trace parameters and syntax, refer to "Chapter 6. Testing and Diagnosis" on page 65.

**Note:** Use of the trace parameters may affect MVSSERV performance. Therefore, your installation may decide not to use the MVSSERV trace parameters for regular production work. However, for testing or diagnosing servers, or requesting diagnosis help from IBM service personnel, use MVSSERV with the trace data set and the parameter TRACE or IOTRACE.

### Dump Data Set

You can allocate a data set to receive dump data from an MVSSERV session. If you allocate a dump data set, MVSSERV provides a dump at the first occurrence of an abend.

## Additional MVSSERV Data Sets

### Allocating the Dump Data Set

The dump data set must be associated with one of the following ddnames:

- SYSUDUMP, for a formatted dump of the MVSSERV storage area
- SYSMDUMP, for an unformatted dump of the MVSSERV storage area and the system nucleus
- SYSABEND, for a formatted dump of the MVSSERV storage area including the local system queue area and IOS control blocks

The exact contents of a dump depend on the default options specified in your SYS1.PARMLIB members SYSUDUMP, SYSMDUMP, and SYSABEND. These system default options can be changed using the CHNGDUMP command. For further information about the dump data sets and how to read them, refer to *z/OS MVS Diagnosis: Tools and Service Aids*.

To make a dump data set available to an MVSSERV user, install the existing data set in the user's logon procedure, or in a CLIST, REXX exec, or ISPF dialog that issues MVSSERV for the user. Each user must have their own dump data set.

- In a logon procedure, you can use the following JCL:

```
//SYSUDUMP DD DSN=data_set_name,DISP=OLD
```

- In a CLIST, REXX exec, or ISPF dialog, you can use the following command:

```
ALLOCATE FILE(SYSUDUMP) DA('data_set_name') OLD
```

## Dump Suppression Data Set

If you use a dump data set, you can eliminate unnecessary dumps by using the MVSSERV dump suppression data set. The dump suppression data set lets you specify abend codes for which you do not want to receive dumps from MVSSERV. For example, you can specify abend code 913 to avoid dumps caused by unsuccessful OPEN macro requests.

### Allocating the Dump Suppression Data Set

The dump suppression data set must have the following characteristics:

- ddname -- CHSABEND
- logical record length -- 80
- format -- fixed or fixed block

You can create the dump suppression data set with the following command:

```
ALLOCATE FILE(CHSABEND) DA('data_set_name') NEW LRECL(80) RECFM(F)
```

To make the dump suppression data set available to an MVSSERV user, allocate the existing data set in the user's logon procedure, or in a CLIST, REXX exec, or ISPF dialog that issues MVSSERV for the user.

- In a user's logon procedure, you can use the following JCL:

```
//CHSABEND DD DSN=data_set_name,DISP=SHR
```

- In a CLIST, REXX exec, or ISPF dialog, you can use the following command:

```
ALLOCATE FILE(CHSABEND) DA('data_set_name') SHR
```

### Initializing the Dump Suppression Data Set

Each 80-byte record of the dump suppression data set must be in the following format:

OFFSET	LENGTH	DESCRIPTION
+0	3	EBCDIC ABEND code in hex. for system ABENDs in decimal for user ABENDs

## Additional MVSSERV Data Sets

+3	1	Reserved
+4	4	EBCDIC REASON code (hex)
+8	1	Reserved
+9	1	EBCDIC dump action field: 0 = Do not dump 1 = SNAP Dump
+10	70	Reserved

Use leading zeros for abend and reason codes as needed. For example, to suppress dumps from abends of the OPEN macro (abend code 913) caused by RACF authorization failure (reason code 38), type the following on a line of the dump suppression data set:

-----1-----2-----3-----4-----5---

913 0038 0

You can replace the first character of the abend code and the entire reason code with X's, to signify all values. For example, to suppress dumps from all reason codes of the OPEN macro, type the following:

-----1-----2-----3-----4-----5---

913 XXXX 0

And to suppress dumps for all abend codes ending in 13, type the following:

-----1-----2-----3-----4-----5---

X13 XXXX 0

For a list of abend and reason codes, refer to the following:

- *z/OS MVS System Codes*
- *z/OS MVS System Messages, Vol 1 (ABA-AOM)*
- *z/OS MVS System Messages, Vol 2 (ARC-ASA)*
- *z/OS MVS System Messages, Vol 3 (ASB-BPX)*

## Chapter 6. Testing and Diagnosis

Testing Servers . . . . .	65
Steps for Testing Servers . . . . .	65
Diagnosing Servers . . . . .	66
Reading the Trace Data Set . . . . .	66

This chapter describes the steps to follow to test servers and diagnose any server problems.

---

### Testing Servers

After you have written and installed a server, you must test it. You can first test the server as a member of a STEPLIB. When you are satisfied that the server works correctly, you can then re-install and test the server again for general use in a system library.

When testing a server, you must start an MVSSERV session on TSO/E. On the PC, you must invoke the requester program that requests the server. The requester must name the server and service function, and pass any data and parameters that the service function needs.

### Steps for Testing Servers

Use the following steps to test a server:

1. Make sure that you have the following data sets available for your MVSSERV session:
  - The server and its initialization/termination program, installed in a STEPLIB in your logon procedure.
  - An input parameter data set, containing the name of the initialization/termination program.
  - A trace data set, to receive MVSSERV messages.

For information about allocating the data sets, refer to “Chapter 5. Installing Programs and Data Sets for Use with MVSSERV” on page 59. You may also want to have the dump data set and the dump suppression data set described in “Chapter 5. Installing Programs and Data Sets for Use with MVSSERV” on page 59.

2. To start the MVSSERV session, log on to TSO/E and issue the MVSSERV command.

MVSSERV has the following syntax, with the default underlined:

```
MVSSERV      [ NOTRACE ]  
              [ TRACE   ]  
              [ IOTRACE ]
```

For the test, use the TRACE option. TRACE produces messages in the trace data set about internal MVSSERV events, including server failures.

**Note:** The method used to refresh the MVSSERV logo depends on your type of terminal support.

3. Switch to the PC session. (If you are using a PC other than the 3270 PC, issue the appropriate Enhanced Connectivity Facility command for the PC.)
4. Invoke the requester that corresponds to the server you want to test.

## Testing Servers

5. Respond to any messages from the requester. The requester should issue messages about any non-zero return codes from the server.
6. Verify that the request was satisfied.
7. Switch back to the host session and press the PF3 key to end MVSSERV.
8. Note any messages that appear on your screen. Each message has a message ID, beginning with CHS. In TSO/E, you can obtain online help for MVSSERV messages by typing the message ID in the following command:  
`HELP MVSSERV MSG(CHSxxxxxxx)`
9. Read the trace data set. Because you used the TRACE option when invoking MVSSERV, the trace data set should have recorded informational and error messages about events in the session and any errors that may have occurred. The trace data set should also contain any messages that the server issued with the default, TRACE, or BOTH options of the CHSTRACE macro.  
For information about reading the trace data set messages, see “Diagnosing Servers”.
10. When the server works properly, you may want to copy it to a system library such as SYS1.LPALIB to make it available to other users. Make sure that the other users allocate the input parameter data set in their logon procedures, in a CLIST, REXX exec, or ISPF dialog, or in line mode TSO/E. After you copy the server to a system library, be sure to retest it.

---

## Diagnosing Servers

This topic describes how to use information in the MVSSERV trace data set to diagnose and correct server problems.

### Reading the Trace Data Set

When MVSSERV is issued with the TRACE or IOTRACE option, the trace data set contains messages from MVSSERV and any messages issued from servers, initialization/termination programs, or access method drivers using the CHSTRACE macro with options TRACE or BOTH.

To see messages about your most recent MVSSERV session, you can edit, browse, or print the MVSSERV trace data set. For explanations of the messages from MVSSERV, see *z/OS TSO/E Messages*.

The message explanations include information about what action, if any, you must take when you see a message.

The MVSSERV messages are preceded by message IDs beginning with the letters CHS. The last character of the message ID indicates the type of message: I for informational messages, and E for error messages.

#### Informational Messages

Informational messages provide information about the status of the MVSSERV session and data transmissions. Informational messages also describe exception conditions, such as server failures, which do not cause MVSSERV to end.

#### Error Messages

Error messages describe conditions that cause MVSSERV to end abnormally. The conditions may be internal MVSSERV errors, system errors, or input errors. Possible input errors include incorrect syntax of the MVSSERV command, a missing input parameter data set, or an CPRB address that was not valid.

Internal errors and system errors often require help from IBM service personnel, but you may be able to correct input errors by following directions in the message explanations.

### The Internal Execution Path Trace Table

The last message in the trace data set, CHSTTP02I, displays MVSSERV's internal execution path trace table. MVSSERV makes an entry in the table whenever one MVSSERV module calls another. Thus, the table provides a history of MVSSERV module calls and makes it possible to track internal MVSSERV errors.

Figure 18 shows a sample of a trace data set obtained using the TRACE option of MVSSERV. The message IDs are in the left-hand column of the figure.

---

```

CHSCMI02I The control unit supports Read Partitioned Queries.
CHSTCA13I DFT access method driver is active.
CHSTRR01I CPRB request at 12:37:07 server=SERVER2 function=0001:
CHSRUTR06I Server request failed; SERVER2 is in an inactive task.
CHSDCOM09I User pressed the PF3 key, requesting termination.
CHSCPS08I MVSSERV is ending.
CHSTTP01I Internal trace table follows. Last entry is 019:
CHSTTP02I 000 TIOR    001 TIOR    002 TIOR    003 TIOR
CHSTTP02I 004 TIOR    005 TIOR    006 TIOR    007 TIOR
CHSTTP02I 008 TIOR    009 TIOR    010 TIOR    011 TIOR
CHSTTP02I 012 TIOR    013 TIOR    014 TIOR    015 TIPM

CHSTTP02I 020 TSRV    021 TRUTR   022 TRUTR   023 TRUTR
CHSTTP02I 024 TRUTR   025 TCMI     026 TLMP    027 TIOR
CHSTTP02I 028 TDCA    029 HRES     030 TDCOM   031 TCH7
CHSTTP02I 032 TC7H    033 PACK    034 TINF    035 TTRL
CHSTTP02I 036 TLMP    037 TIOR    038 HQNL    039 TDCOM
      :
```

---

*Figure 18. Sample Trace Data Set*

For explanations of messages that appear in your MVSSERV trace data set, look up the message ID (CHSxxxxxxx) in *z/OS TSO/E Messages*.

The message explanations tell what happened and why, and tell what action you should take (if any) to correct a problem.

## Diagnosing Servers

---

## Chapter 7. Macro Syntax and Parameters

CHSDCPRB Macro . . . . .	69
Accessing the CPRB. . . . .	69
Creating a CPRB for the DEFSEVR or SENDREQ Macro . . . . .	70
CHSCED Macro . . . . .	70
INITTERM Macro . . . . .	70
DEFSEVR Macro . . . . .	71
Register Contents for DEFSEVR . . . . .	72
DEFSEVR Syntax and Parameters . . . . .	72
The DEFSEVR CPRB . . . . .	73
SENDREQ Macro . . . . .	73

SENDREQ Syntax and Parameters . . . . .	74
The SENDREQ CPRB . . . . .	76
CHSTRACE Macro . . . . .	76
CHSTRACE Considerations . . . . .	76
CHSTRACE Syntax and Parameters . . . . .	77

This chapter describes the syntax and parameters of the following MVSSERV macros:

*Table 7. MVSSERV Macros*

Macro	Function	On page:
CHSDCPRB	CPRB mapping macro	69
CHSCED	CED mapping macro	70
INITTERM	INITTERM mapping macro	70
DEFSEVR	Server definition macro	71
SENDREQ	Send request macro	73
CHSTRACE	Message issuing macro	76

---

### CHSDCPRB Macro

The CHSDCPRB macro provides a CPRB mapping DSECT or builds code to acquire storage for and partially initialize a CPRB control block. You can use the CHSDCPRB macro to:

- Access the fields of a CPRB to obtain service request input.
- Create a CPRB to use with the DEFSEVR or SENDREQ macros.

### Accessing the CPRB

Servers receive service request input in the CPRB. A server can use the CHSDCPRB macro to access the fields of a CPRB to obtain the input. To access a CPRB, use the CHSDCPRB macro with the following syntax:

```
[label] CHSDCPRB [DSECT=YES|NO]
```

Code the macro with DSECT=YES (or omit the DSECT parameter) to build a DSECT for the CPRB fields. You can use the label CHSDCPRB to address the CPRB with an assembler USING statement. For an example of using the CHSDCPRB macro to access a CPRB, see “Sample Servers” on page 12. Table 1 on page 9 shows the service request CPRB that servers access using macro CHSDCPRB.

## CHSDCPRB Macro

### Creating a CPRB for the DEFSERV or SENDREQ Macro

Before issuing the DEFSERV or SENDREQ macro, a program must create a CPRB. To create a CPRB, you can use the CHSDCPRB macro with the following syntax:

```
[label] CHSDCPRB DSECT=NO
```

**Note:** If the program is reentrant, use the GETMAIN macro to obtain storage for the CPRB.

For an example of using the CHSDCPRB macro with DEFSERV, see “Sample Initialization/Termination Program” on page 42.

For an example of using the CHSDCPRB macro with SENDREQ, see “Sample Servers” on page 12.

A program can use the same CPRB repeatedly to define multiple servers or send multiple requests. Therefore, a program only needs to issue the CHSDCPRB macro once to create one CPRB.

If you use the CHSDCPRB macro to obtain storage for the CPRB dynamically, the storage is freed when the program ends. If you use the GETMAIN macro to obtain storage, you must use the FREEMAIN macro to release it.

---

## CHSCED Macro

MVSSERV's connectivity environment descriptor (CED) contains addresses that must be included in the DEFSERV, SENDREQ, and CHSTRACE macros. Programs can use the CHSCED mapping macro to obtain these addresses from the CED. The CHSCED macro has the following syntax:

```
[label] CHSCED [DSECT=YES|NO]
```

Code the macro with DSECT=YES (or omit the DSECT parameter) to build a DSECT that maps the CED fields. You can use the label CHSCED to address the control block with an assembler USING statement. For an example of using the CHSCED macro see “Sample Servers” on page 12.

Table 8 shows the fields of the CED.

*Table 8. Connectivity Environment Descriptor (CED)*

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	4	CEDROUT	Address of router for DEFSERV and SENDREQ requests.
4(4)	8		Reserved
12(C)	4	CEDTRCE	Address of trace facility for CHSTRACE requests.
16(10)	80		Reserved

---

## INITTERM Macro

The INITTERM control block provides input to server initialization/termination programs when MVSSERV begins and ends. Use the INITTERM mapping macro in an initialization/termination program to access fields of the INITTERM control block. The INITTERM macro has the following syntax:

[label] INITTERM [DSECT=YES|NO]

Code the macro with DSECT=YES (or omit the DSECT parameter) to build a DSECT that maps the control block fields. You can use the label INITTERM to address the control block with an assembler USING statement. For an example of using the INITTERM macro, see “Sample Initialization/Termination Program” on page 42.

Table 9 shows the INITTERM control block. Note that some fields contain input for termination only.

Table 9. INITTERM Control Block

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	4	INTINIT	Initialization or termination indicator. X'0000' indicates initialization; X'0001' indicates termination.
4(4)	4	INTWALEN	Work area length. The length of a work area, if any, specified at initialization.
8(8)	4	INTWAPTR	Work area address. The address of a work area, if any, specified at initialization.
12(C)	8	INTSNAME <sup>1</sup>	Name of the last server that sent a reply. If the initialization/termination program defined this server and the last reply was not received successfully (see INTRSN), the initialization/termination program may take appropriate action; for example, cancelling the last service performed.
20(14)	4	INTRSN <sup>1</sup>	Return code for last reply. Contains one of the following return codes:  <b>0(0)</b> Processing was successful. <b>4(4)</b> The last reply <i>may not</i> have been successfully received by the requester. <b>8(8)</b> The last reply was not successfully received by the requester. <b>10(A)</b> The last reply CPRB from the server was not valid.
24(18)	4	INTENVRN	Reserved
28(1C)	4		CPPL address. The CPPL must be in register 1 if a program invokes a TSO/E command processor or uses TSO/E services such as SCAN or PARSE.
32(20)	4		Reserved

*Note:*

<sup>1</sup> Input for termination only.

## DEFSERV Macro

To define servers to MVSSERV, use the DEFSERV macro. Initialization/termination programs can issue the DEFSERV macro to define servers, and servers can also issue the DEFSERV macro to define other servers.

## DEFSERV Macro

### Register Contents for DEFSERV

Before issuing the DEFSERV macro, you must set register 13 to point to a 72-byte save area:

#### Register 13

Address of a standard 72-byte save area

There are no requirements for the other registers. However, the DEFSERV macro may change the contents of the following registers: 0, 1, 14, 15.

### DEFSERV Syntax and Parameters

Table 10 shows the syntax of the DEFSERV macro. For an example of the DEFSERV macro, see Figure 14 on page 43.

Table 10. DEFSERV Macro Syntax

EXECUTE FORM		
label	DEFSERV	CPRB=address, CED=address, SERVNAME=server_name, SERVEPA=server_address, SERVPARM=parmlist_address MF=(E,plist_name)
LIST FORM		
plist_name	DEFSERV	MF=L
<b>Note:</b> The addresses can be any address valid in an RX instruction, or the number of a general register (2–12) enclosed in parentheses. The addresses must be in the same addressing mode (AMODE) as the issuing program.		

#### Execute Form

##### CPRB=address

Specify the address of the DEFSERV CPRB. The CPRB must begin on a fullword boundary.

##### CED=address

Specify the address of the CED that was passed as input to the issuing program. (To map the CED, use the CHSCED macro.)

##### SERVNAME=server\_name

Specify the name of the server being defined. You can also specify a general register (2–12) that points to an 8-byte field containing the server name. To do so, enclose the register number in parentheses. This name is passed to MVSSERV in the CRBSNAME field of the DEFSERV CPRB.

##### SERVEPA=server\_address

Specify the address of the server being defined. If this program loaded the server, obtain the address from the LOAD macro. If you do not obtain the address from the LOAD macro, and the server is AMODE 31, be sure to specify the address with the high-order bit set to 1.

##### SERVPARM=parmlist\_address

Specify the address of a server parameter list (parmlist). If no parmlist is desired, code SERVPARM=0. The server parmlist should point to any resources that the issuing program obtained for the server, such as shared data sets and storage. MVSSERV passes this parmlist to the server when it calls the server to handle a service request.

**MF=(E,plist\_name)**

Specify the name of a 20-byte area that will contain the DEFSERV parameter list (plist):

- The addresses of the CPRB and CED (8 bytes)
- The server entry point address and server parmlist address (the *define server parameter area* -- 12 bytes).

## List Form

**plist name MF=L**

generates 20 bytes of storage to contain the addresses of the CPRB and CED (8 bytes) and the define server parameter area (12 bytes). The DEFSERV macro fills in this storage. The label on this statement must match the DEFSERV **plist name** used in the MF keyword of the execute form of the macro.

**Note:** If the issuing program is reentrant, it must use the GETMAIN macro to allocate the 20 bytes of storage, and the FREEMAIN macro to release the storage when finished processing.

## The DEFSERV CPRB

The DEFSERV macro fills in a CPRB as shown in Table 11. The DEFSERV macro sends the CPRB to MVSSERV, which uses the CPRB to identify the server name with the server's address and parmlist.

Table 11. CPRB Control Block Used to Define a Server

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	1	CRBF1	The control block's version number (first four bits) and modification level number (last four bits).
1(1)	2		Reserved
3(3)	1	CRBF4	The type of request (X'03' indicates a Define Server request).
4(4)	4	CRBCPRB	The value of C'CPRB'.
8(8)	8		Reserved
16(10)	8	CRBSNAME	The server name specified in the DEFSERV parameter SERVNAME.
24(18)	32		Reserved
56(38)	4	CRBRQPLN	The value X'03', indicating the length of the define server parameter area.
60(3C)	4	CRBRQPRM	The address of the define server parameter area.
64(40)	48		Reserved

For a list of return codes from the DEFSERV macro, see "Chapter 8. MVSSERV Return Codes" on page 79.

## SENDREQ Macro

To send service requests to servers that are defined in the current MVSSERV session, use the SENDREQ macro. Servers, initialization/termination programs, and access method drivers can issue the SENDREQ macro.

## SENDREQ Macro

### Register Contents for SENDREQ

Before issuing the SENDREQ macro, you must set register 13 to point to a 72-byte save area:

#### Register 13

Address of a standard 72-byte save area

There are no requirements for the other registers. However, the SENDREQ macro may change the contents of the following registers: 0, 1, 14, 15.

### SENDREQ Syntax and Parameters

Table 12 shows the syntax of the SENDREQ macro. Optional parameters are enclosed in brackets. For an example of the SENDREQ macro, see Figure 6 on page 14.

Table 12. SENDREQ Macro Syntax

#### EXECUTE FORM

```
label SENDREQ CPRB=name or address,  
              CED=name or address,  
              SERVER=name or address,  
              [FUNCTION=name or address,]  
              [REQPARM=(address,length),]  
              [REQDATA=(address,length),]  
              [REPPARM=(address,length),]  
              [REPDATA=(address,length),]  
              [RETCODE=address,]  
              MF=(E,plist_address[,COMPLETE])
```

#### LIST FORM

```
SENDREQ MF=(L,plist_address[,attr])
```

**Note:** The addresses can be any address valid in an RX instruction, or the number of a general register (2)–(12) enclosed in parentheses. Addresses must be in the same addressing mode (AMODE) as the issuing program.

### Execute Form

#### CPRB=name or address

Specify the name, or address in a register (2–12), of the CPRB control block. The CPRB must be obtained by the invoker of SENDREQ and must begin on a fullword boundary. (To map the CPRB, use the CHSDCPRB macro.)

#### CED=name or address

Specify the name, or address in a register (2–12), of the CED that was passed as input to the invoking program. (To map the CED, use the CHSCED macro.)

#### SERVER=name or address

Specify the name, or address in a register (2–12), of an field containing the name of the server to which the request is being sent. The maximum length of the field is eight characters.

#### [FUNCTION=name or address]

Specify the name, or address in a register (2–12), of a 2-byte field containing the function ID of the service function being requested. If FUNCTION is omitted, it defaults to 0.

#### [REQPARM=(address,length)]

Specify data describing the request parameter list to be passed to the server.

Provide the names, or addresses in registers (2–12), of a 4-byte field containing the address and a 4-byte field containing the length of the request parameter list. The maximum length is 32763 bytes. If address or length is omitted, it defaults to 0. If REQPARM is omitted, no request parameter list is passed.

**[REQDATA=(*address,length*)]**

Specify data describing the request data area to be passed to the server.

Provide the names, or addresses in registers (2–12), of a 4-byte field containing the address and a 4-byte field containing the length of the request data area. The maximum length is 65535 bytes. If address or length is omitted, it defaults to 0. If REQDATA is omitted, no request data area is passed.

**[REPPARM=(*address,length*)]**

Specify data describing the reply parameter area to be passed to the server.

Provide the names, or addresses in registers (2–12), of a 4-byte field containing the address and a 4-byte field containing the length of the reply parameter list. The maximum length is 32763 bytes. If address or length is omitted, it defaults to 0. If REPPARM is omitted, no reply parameter list is passed.

**[REPDATA=(*address,length*)]**

Specify data describing the reply data area to be passed to the server.

Provide the names, or addresses in registers (2–12), of a 4-byte field containing the address and a 4-byte field containing the length of the reply data area. The maximum length is 65535 bytes. If address or length is omitted, it defaults to 0. If REPDATA is omitted, no reply data area is passed.

**[RETCODE=*variable*]**

Specify the name or address of a 4-byte output variable to receive the SENDREQ return code from register 15. If you omit this parameter, you must obtain the return code from register 15.

**MF=(*E,plist\_address*[,**COMPLETE**])**

specifies the execute form of the macro and the address of a storage area for the macro parameter list. The execute form generates code to put the parameters into a parameter list and invoke the desired server.

**[**COMPLETE**]**

MVSSERV performs complete syntax checking, verifying that required SENDREQ parameters are specified and supplying default values for omitted optional parameters.

## List Form

**MF(*L,plist\_address*[,*attr*])**

Specify the list form of the macro and the address of a storage area for the macro parameter list. The list form defines an area to contain the parameter list.

**[*attr*]**

Specify an optional input string that contains any special attributes for the parameter list, such as its word boundary. The maximum length of the string is 60 characters. If omitted, the default is BDY(DWORD).

**Note:** If the issuing program is reentrant, it must use the GETMAIN macro to allocate the storage area for the parameter list and the FREEMAIN macro to release the storage.

## SENDREQ Macro

### The SENDREQ CPRB

The SENDREQ macro fills in a CPRB as shown in Table 13. The SENDREQ macro sends the CPRB to MVSSERV, which routes the CPRB to the requested server.

Table 13. CPRB Control Block for Sending a Request (SENDREQ)

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	1	CRBF1	The control block's version number (first four bits) and modification level number (last four bits).
1(1)	2		Reserved
3(3)	1	CRBF4	The type of request. X'01' indicates a service request. (X'03' indicates a define server (DEFSERV) request.)
4(4)	4	CRBCPRB	Control block identifier ('CPRB').
8(8)	8		Reserved
16(10)	8	CRBSNAME	The name of the requested server.
24(18)	2		Reserved
26(1A)	2	CRBFID	The ID number of the requested service function.
28(1C)	12		Reserved
40(28)	4	CRBRQDLN	The length of the request data.
44(2C)	4	CRBRQDAT	The address of the request data.
48(30)	4	CRBRPDLN	The length of the reply data (maximum length allowed by the invoker of SENDREQ).
52(34)	4	CRBRPDAT	The address of the buffer for reply data.
56(38)	4	CRBRQPLN	The length of the request parameters.
60(3C)	4	CRBRQPRM	The address of the request parameters.
64(40)	4	CRBRPPLN	The length of the reply parameters (maximum length allowed by the invoker of SENDREQ).
68(44)	4	CRBRPPRM	The address of the buffer for reply parameters.
72(48)	40		Reserved

For a list of return codes from the SENDREQ macro, see “Chapter 8. MVSSERV Return Codes” on page 79.

## CHSTRACE Macro

To issue messages to the terminal, the MVSSERV trace data set, or both, use the CHSTRACE macro. Servers, initialization/termination programs, and access method drivers can issue the CHSTRACE macro.

### CHSTRACE Considerations

Messages from CHSTRACE must not exceed 80 characters in length. Any messages over 80 characters long are truncated after the 80th character.

Messages must begin with a message ID or a blank character. If an MVSSERV user has PROFILE NOMSGID specified, TSO/E removes the message ID or any other characters preceding the first blank character in the message.

## CHSTRACE Syntax and Parameters

Table 14 shows the syntax of the CHSTRACE macro. Optional parameters are shown in brackets. For an example of the CHSTRACE macro, see Figure 6 on page 14.

Table 14. CHSTRACE Macro Syntax

<b>EXECUTE FORM</b>	
label CHSTRACE	[DEST=[TRACE TERM BOTH],] CED=name or address, BUFFER=name or address, BUFLen=name or address, [RETCODE=variable,] MF=(E,plist_address[,COMPLETE])
<b>LIST FORM</b>	
CHSTRACE	MF=(L,plist_address[attr])
<b>Note:</b> The addresses can be any address valid in an RX instruction, or the number of a general register (2–12) enclosed in parentheses.	

### Execute Form

#### [DEST=[TRACE | TERM | BOTH],]

Specify the destination of the message. TRACE sends the message to the MVSSERV trace data set. TERM sends the message to the terminal. BOTH sends the message to both the terminal and the trace data set. If you omit this parameter, messages go to the trace data set.

#### CED=name or address

Specify the name, or address in a register (2–12), of the CED that was passed as input to the invoking program. To map the CED, use the CHSCED macro.

#### BUFFER=name | address

Specify the name, or address in a register (2–12), of a message buffer that the macro is to issue.

#### BUFLen=address

Specify the name, or address in a register (2–12), of a 4-byte field that contains the length in bytes of the message buffer to be issued. The maximum buffer length is 80 bytes. Messages that exceed 80 characters in length are truncated.

#### [RETCODE=variable]

Specify the name or address of a 4-byte output variable to receive the CHSTRACE return code from register 15. If you omit this parameter, you must obtain the return code from register 15.

#### MF=(E,plist\_address[,COMPLETE])

specifies the execute form of the macro and the address of a storage area for the macro parameter list. The execute form generates code to put the parameters into a parameter list and invoke the desired server.

#### [,COMPLETE]

MVSSERV performs complete syntax checking, verifying that required CHSTRACE parameters are specified and supplying default values for omitted optional parameters.

## CHSTRACE Macro

### List Form

**MF(L,plist\_address[,attr])**

specifies the list form of the macro and the address of a storage area for the macro parameter list. The list form defines an area to contain the parameter list.

**[,attr]**

Specify an input string that contains any special attributes for the parameter list. The maximum length of the input string is 60 characters. If omitted, the default is BDY(DWORD).

**Note:** If the issuing program is reentrant, it must use the GETMAIN macro to allocate the storage area for the parameter list and the FREEMAIN macro to release the storage.

For a list of return codes from the CHSTRACE macro, see “Chapter 8. MVSSERV Return Codes” on page 79.

---

## Chapter 8. MVSSERV Return Codes

Return Codes from the DEFSEVR Macro . . . . .	79
Return Codes from the DEFSEVR CPRB . . . . .	79
Return Codes from the SENDREQ Macro . . . . .	80
Return Codes from the SENDREQ CPRB . . . . .	80
Return Codes from the CHSTRACE Macro . . . . .	81

This chapter lists return codes from the DEFSEVR, SENDREQ, and CHSTRACE macros.

---

### Return Codes from the DEFSEVR Macro

When a program resumes control after issuing the DEFSEVR macro, the program must inspect register 15 for a return code from MVSSERV. The possible return codes are shown in Table 15.

*Table 15. Return Codes from the DEFSEVR Macro*

Return Code Dec(Hex)	Meaning
0(0)	The DEFSEVR request was successful.
4(4)	The DEFSEVR request was unsuccessful. The program must inspect the MVSSERV return code in the CPRB (field CRBCRTNC) to determine the cause of the failure. See "Return Codes from the DEFSEVR CPRB".
8(8)	The CPRB is not valid. Data fields in the CPRB, such as CPRBF4, contained information that was not valid.
12(C)	The CPRB is not valid. 24-bit addresses are not valid (the high-order byte of the addresses was not 0).
16(10)	The CPRB is not valid. The address of the CPRB or addresses within the CPRB are not valid, causing MVSSERV to fail.

### Return Codes from the DEFSEVR CPRB

If the return code in register 15 is 4, the program must check for an additional return code in the DEFSEVR CPRB, which MVSSERV returns after finishing with the DEFSEVR macro. The additional return code, if any, is in field CRBCRTNC, as shown in Table 16.

*Table 16. Return Codes in the DEFSEVR CPRB*

Offset Dec(Hex)	Number of Bytes	Field Name	Contents or Meaning
0(0)	12		Reserved
12(C)	4	CRBCRTNC	The return code from MVSSERV in response to the DEFSEVR request CPRB. Contains one of the following return codes: <b>0000</b> Processing was successful. <b>0148</b> Request failed; another defined server has the same name. <b>0152</b> Request failed; MVSSERV error.
16(10)	96		Reserved

## Return Codes from the SENDREQ Macro

When a program resumes control after issuing the SENDREQ macro, the program must inspect register 15, or the variable defined in the RETCODE parameter, for a return code from MVSSERV. The possible return codes are shown in Table 17.

Table 17. Return Codes from the SENDREQ Macro

Return Code Dec(Hex)	Meaning
0(0)	The request was successfully routed.
4(4)	The request was unsuccessfully routed. The program must inspect the MVSSERV return code in the CPRB (field CRBCRTNC) to determine the cause of the failure. See “Return Codes from the SENDREQ CPRB”.
8(8)	The CPRB is not valid. Data fields in the CPRB, such as CPRBF4 (function ID), contained information that was not valid.
12(C)	The CPRB is not valid. 24-bit addresses are not valid (the high-order byte of the addresses was not 0).
16(10)	The CPRB is not valid. The address of the CPRB or addresses within the CPRB are not valid, causing MVSSERV to fail.

## Return Codes from the SENDREQ CPRB

If the return code in register 15 is 4, you must check for an additional return code in the CPRB, which MVSSERV returns after handling the SENDREQ macro. The additional return code, if any, is in field CRBCRTNC.

The return codes and their meanings are shown in Table 18.

Table 18. Return Codes in the SENDREQ CPRB

Offset Dec(Hex)	Number of Bytes	Field Name	Contents
0(0)	12	CRBCRTNC	Reserved
12(C)	4		The return code from MVSSERV in the SENDREQ reply CPRB:
			<b>0000</b> Processing was successful.
			<b>0130</b> Request failed; the server was not found.
			<b>0131</b> Request failed; the server was unavailable.
			<b>0132</b> Request failed; the reply parameter length was not valid.
			<b>0133</b> Request failed; the reply data length was not valid.
			<b>0135</b> Request failed; the requested server failed.
			<b>0136</b> Request failed; MVSSERV error.
16(10)	96		Reserved

---

## Return Codes from the CHSTRACE Macro

When a program resumes control after issuing the CHSTRACE macro, the program must inspect register 15, or the variable defined in the RETCODE parameter, for a return code from MVSSERV. The possible return codes are shown in Table 19.

*Table 19. Return Codes from the CHSTRACE Macro*

Return Code Dec(Hex)	Meaning
0(0)	The message was successfully issued (to the terminal, the trace data set, or both).
4(4)	A failure occurred in message processing. Check the syntax of the CHSTRACE macro and the allocation of the trace data set.

## Return Codes from the CHSTRACE Macro
